These plots of the mean and worst measurements for each field over the resultant diagnosis show a relatively consistent pattern of higher measurements resulting in more malignant diagnoses. Since the worst and mean relationships are intimately related to one another and to the standard error, it makes sense that the plots show direct correlation between statistics for many of the variables.

We can expect standard errors to be higher for observations where the worst measurement is >> than the mean of all measurements, but in this case, we left standard error out of the visualizations for the sake of clarity.

Form Training and Test Data Sets

```
# set random seed
set.seed(1847)
p <- 0.2 # proportion of test data
m <- 569 # number of observations

train_inds <- sample.int(m, (1-p)*m)
train_d <- cancer_data[train_inds,]
test_d <- cancer_data[-train_inds,]

dim(train_d)

## [1] 455 32
dim(test_d)

## [1] 114 32</pre>
```

Model Evaluation Function

Pruning the decision tree by penalizing branches that didn't greatly improve the model accuracy ended up creating a much simpler model that only required one split to correctly categorize 87% of the test data. This is pretty interesting because it means that almost 90% of the decision in this decision tree is just looking at the worst area measurements to determine if a tumor is benign or malignant. One thing we may want to consider in this pruned model is that the simpler tree produced more false negatives, incorrectly predicting that a malignant tumor was benign. Since it would always be better in this situation to have false positive that start getting treated than false negatives that never get treated, it may be worth the added complexity of the original model if it can decrease the rate of false negatives.

Random Forest Classification

Training Model on All

```
# set random seed
set.seed(1847)

# get data in form for random forest model
train_rf <- train_d %>% select(-diagnosis)
y_rf <- as.factor(train_d$diagnosis)
test_rf <- test_d %>% select(-diagnosis)
ytest_rf <- as.factor(test_d$diagnosis)

# create random forest model
rfm <- randomForest(x = train_rf, y = y_rf)
rfm

##
## Call:</pre>
```

```
## randomForest(x = train_rf, y = y_rf)
## Type of random forest: classification
## No. of variables tried at each split: 5
##
## OOB estimate of error rate: 3.52%
## Confusion matrix:
## B M class.error
## B 280 5 0.01754386
## M 11 159 0.06470588
```

Performance Evaluation

```
# generate predictions and confusion matrix for random forest model
confusion_eval(mod = rfm, test = test_rf, y = ytest_rf)
```

```

Model Performance by nTrees and mVariables

All of the models tested ended up with metrics that all fell between 93-99%. While all the models performed well, we wanted to select a model that would reduce the risk of false negatives (in favor of false positives), since it would be far more dangerous to have a malignant tumor misdiagnosed as benign. Since a high sensitivity indicates a lower rate of false negatives to true positives, we wanted to prioritize a high sensitivity over accuracy and precision. Among the models that scored the best in sensitivity, accuracy and precision

(respectively), the simplest was the model with 10 trees trained with 10 variables each.

Choose Top Perfoming Random Forest

```
top_rf_model <- rf_models$`mtry: 10 ntree: 10`</pre>
top_rf_model
##
## Call:

```

Choosing Top Performing KNN

scale_x_continuous(breaks = c(1,2,3,4,5,6,7), labels = ks) +
theme_bw()

Performance of kNN model for different values of k

Given that we want to find a model that is accurate but also prioritizes sensitivity over precision (since it would be more dangerous to falsely conclude that a tumor is benign than to falsely conclude that a tumor is malignant), we would want to choose the model for k=1. While k=1 had the highest rate of false positives on this data set, it also had the lowest rate of false negatives, meaning that it would be unlikely to falsely conclude that a tumor is benign when it is actually malignant. Even so, the sensitivity was only around 80% in the best case, so this model would probably not work well for our use case.
